

Skeleton Tarantula (Ephebopus murinus)

Tarantulas from Beyond the Grave

This is a medium sized to large, black, brown, to dark colored species with a lighter cream colored carapace and white to cream colored joints and legs, lending to their common name of "skeleton" tarantula. The skeleton tarantula is an obligate burrowing, fossorial species, and like other tarantulas, will often act as ambush predators of insects, other invertebrates, and even small mammals or birds using silk threads to detect potentially approaching prey.

Taxonomy

Life: All living, physical, and animate entities

Domain: Eukaryota Kingdom: Animalia **Phylum:** Arthropoda Subphylum: Chelicerata

Class: Arachnida **Order:** Araneae

Infraorder: Mygalomorphae Family: Theraphosidae

Genus: Ephebopus

Species: *Ephebopus murinus**

*Taxonomy subject to change and revision.

Lifespan and Longevity

Males of many tarantula species will often attain life spans of only 5 to 6 years. Females attain considerably longer life spans of 15 to 20 years or more in captivity.

Distribution and Habitat

The skeleton tarantula is a large, boldly colored and patterned tarantula indigenous to the tropical, wet to semi-wet climates of Brazil, South America.

Conservation Status

Not Evaluated for the IUCN Red List (NE) or otherwise Data Deficient (DD).

Legal and Regulatory Status (*Subject to Change)

Consult with your local, municipal, and state ordinances and regulations for any ownership restrictions.

Experience Level Required

Intermediate/Moderate to Advanced.

Size

Skeleton tarantulas are medium-sized to large tarantulas reaching a total legspan of about 4 to 6 ½ inches on average.

Housing and Enclosure

Provide a sturdy, secure, and escape proof terrarium or enclosure 5 to 10 gallons long in size with a secure top for a single adult spider. Several of the acrylic displays and enclosures that are now manufactured for housing arachnids, insects, and other invertebrates can also be used. Spiderlings can be housed in an appropriately sized spiderling vial, plastic container or deli cup with adequate holes for ventilation. Acceptable substrate to use can include pesticide free potting soil, coconut fiber, vermiculite, or similar substrates 3 to 4 inches in depth. Decorations and/or other cage furnishings can also be included as well, although floor space is more important than height. This is a primarily terrestrial to burrowing species, but benefits from branches, horizontal cork bark, and plants for refuge. A fairly small, shallow water dish can also be provided, and should be cleaned regularly as well as regular misting for hydration.

Temperature, Lighting, and Humidity

Most species of tarantulas have simple and undemanding heating and lighting requirements in captivity, and do not require additional UVA/UVB lighting, although providing it can be greatly beneficial for your tarantula's health, immune system, and overall wellness. Skeleton tarantulas are a fairly hardy species that will tolerate ambient temperatures of as low as 65 degrees F. Typically, however, they may be kept at an ambient temperature of 78 to 82 degrees. Weekly and monthly regular misting will also help maintain humidity. Maintain at 65 to 70% humidity but the enclosure must have adequate ventilation and substrate be kept dry. For any supplemental heating that may be needed, use a low wattage incandescent or UVA/UVB bulb, radiant or ceramic heat emitter, or UTH (under tank heating element). More specific lighting, heating, and humidity product suggestions and recommendations that can best suit one's needs, as well as those of one's animals can be given as well.

Feeding, Diet, and Nutrition

Insectivorous to Carnivorous; In the wild, skeleton tarantulas are primarily insectivorous, meaning they eat insects and other invertebrates. They will also occasionally eat smaller vertebrates as well if they can catch and subdue them. In captivity, these tarantulas can be fed a variety of appropriately sized feeder insects such as crickets, roaches, mealworms, superworms, and waxworms. Feeder insects should be gut-loaded in order to increase their optimal nutritional value. This will promote optimal exoskeleton growth and development. Any uneaten food items should be cleaned and removed after a day or two. Their feeding frequency will depend on the age, size, and overall health of your animal. Use care as to not overfeed even invertebrates, as obesity and other health related issues can still become an issue with them. More specific dietary and supplementary product suggestions and recommendations that can best suit one's needs, as well as those of one's animals can be given as well.

Handling

The skeleton tarantula tends to be a defensive species that can also be fast moving. It is also an obligate burrower, and will not be seen frequently. Although bites from this species are typically not serious or medically significant, they do deliver a painful and unpleasant bite with potentially potent venom and are not suitable spiders for beginners. Therefore, handling these species typically is not recommended. This species is better suited as a more intermediate to advanced spider overall. In general, tarantulas are fragile animals, and accidently dropping a spider can result in the rupture of its internal organs and/or exoskeleton, causing death to your tarantula. Although most tarantulas are not medically significant, with most being lesser than or just about equal to a bee sting, medical attention should still be sought from any apparent allergic reaction to a bite, or extreme irritation from urticating hairs from a pet tarantula, particularly from this genus.

Also be sure to practice basic cleanliness and hygiene associated with proper husbandry after touching or handling any animals or animal enclosures to prevent the possibility of contracting salmonellosis or any other zoonotic pathogens
